## TELEPHONE LINE INTERFACE

### SEMICONDUCTOR TECHNICAL DATA

## Advance Information Telephone Line Interface

The TCA3388 is a telephone line interface circuit which performs the basic functions of a telephone set in combination with a microcontroller and a ringer. It includes dc and ac line termination, the hybrid function with 2 adjustable sidetone networks, handset connections and an efficient supply point.

### FEATURES

#### Line Driver and Supply

- DC and AC Termination of the Telephone Line
- Selectable DC Mask: France, U.K., Low Voltage
- Current Protection
- Adjustable Set Impedance for Resistive and Complex Termination
- Efficient Supply Point for Peripherals
- Hook Status Detection

#### Handset Operation

- Transmit and Receive Amplifiers
- Double Anti-Sidetone Network
- Line Length AGC
- Microphone and Earpiece Mute
- Transmit Amplifier Soft Clipping

#### Dialing and Ringing

- Interrupter Driver for Pulse-Dialing
- Reduced Current Consumption During Pulse-Dialing
- DTMF Interfacing
- Ringing via External Ringer

#### Application Areas

- Corded Telephony
- Cordless Telephony Base Station
- Answering Machines
- Fax
- Intercom
- Modem

18	Gnd	Ground
19	RXO1	Earphone Amplifier Output
20	RXO2	Earphone Amplifier Inverted Output

# TCA3388

## DESCRIPTION OF THE CIRCUIT

### Concept

With a TCA3388, a microcontroller and a ringer, a basic telephone set can be built according to the concept depicted in Figure 1.

In off-hook position, the application is in speech mode. The line current flows through transistor T2 and supplies the externals (microcontroller) at the supply point  $V_{CC}$  which is stabilized by the TCA3388. The  $V_{line}$ ,  $I_{line}$  characteristic is adjusted by the external components Z0, Z1, Z21 and R1 which are in a regulator loop, acting on transistor T2. The ac

impedance is generated in a similar way. The handset can be connected directly to the TCA3388. Via a logic level interface, the microcontroller drives the TCA3388 to perform the DTMF/pulse-dialing. The user keyboard has to be connected to the microcontroller. In on-hook position, a ringing melody can be generated with a ringer application.

The block diagram of the TCA3388, in Figure 2, shows the basic blocks of the device plus the essential external components.

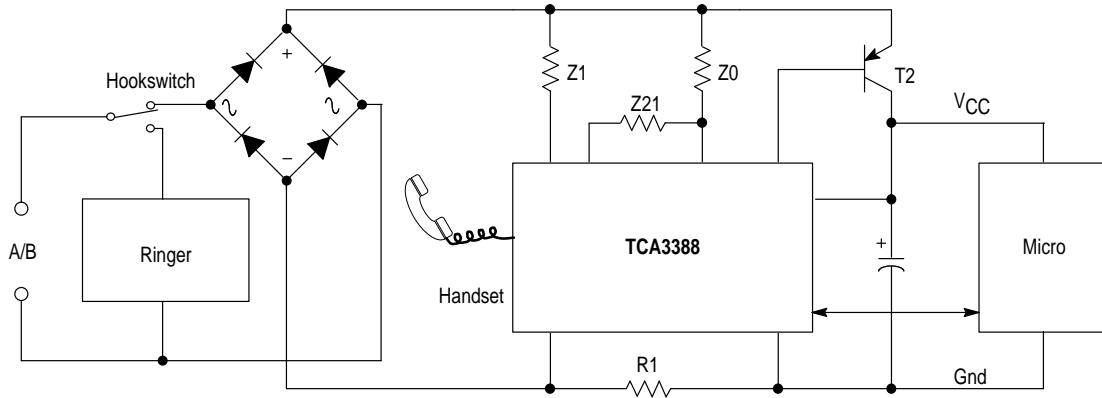

Figure 2. Block Diagram of the TCA3388 with Essential Components

# TCA3388

## DC CHARACTERISTICS AND STARTUP

The dc mask has the general form as depicted in Figure 3.

The TCA3388 offers the possibility to adjust the dc characteristics of all 4 regions via mask selection and hardware adjustments.

The selection of the 3 masks, France, United Kingdom and Low Voltage, can be done via the Z<sub>DCM</sub> network at Pin DCM as shown in Figure 4. For French and U.K. masks, the region 3 with the high slope is within the normal dc feeding conditions. For Low Voltage mask the region 3 will be outside this and the dc mask is mainly determined by regions 1 and 2.

**Figure 4. Selection of the Country Mask via Pin DCM**

**Figure 3. General Form of the DC Mask of the TCA3388**

- Region 1: Startup, Low Line Current, High Slope
- Region 2: Mid-Range Line Current, Low Slope
- Region 3: High Line Current, High Slope
- Region 4: Overload Protection

**Z<sub>DCM</sub> for the L.V., U.K. and FR Mask**

The capacitor in the U.K. network is to ensure a stable selection of the mask during all working modes and transitions. The capacitor in the French network is used to create a startup in Low Voltage Mask.

The adjustment possibilities will be discussed below with the aid of the block diagram of Figure 5.

**Figure 5. DC Part of the Block Diagram of the TCA3388**

The TCA3388 offers the possibility to connect 2 sidetone networks Z1 and Z2. For correct dc operation, the dc impedance of these networks must be equal. When only 1 sidetone network is used, Pin HYS has to be connected to HYL. All formulas below are based on a single sidetone network, so only Z1 appears. When 2 sidetone networks are used, Z1 has to be replaced by Z1//Z2.

In region 1, the transfer of the amplifier G at the HYL/HYS inputs equals zero. The voltage difference between SAO and SAI will equal VO1. The slope RE1 of the VLine, ILine characteristic will equal:

$$R_{E1} = R1 \times \left( 1 + \frac{Z0}{Z21} \right)$$

In region 2, the output current of the amplifier G will be proportional to the input current. As a result the voltage between SAO and SAI will increase with the line voltage. Speech signals on the line are of no influence on this because they are filtered out via capacitor C16. The slope RE2 of the VLine, ILine characteristic will equal:

$$R_{E2} = R1 \times \left[ 1 + \frac{1}{\frac{R1}{Z1} + \frac{Z21}{Z0}} \right]$$

In region 3, the output current of the amplifier G is kept constant. As a result the slope in region 3 will equal the slope of region 1.

The transfer from region 2 to 3 occurs at the point VLK, ILK defined by:

$$V_{LK} = Z1 \times I2CD + 2 V_{BE} + V_{CD} + VO2$$

$$I_{LK} = \frac{\frac{Z21}{Z0} \times (Z1 \times I2CD + 2 V_{BE}) + V_{CD}}{R1}$$

With:  $I2CD = \frac{I2C + I2D}{2}$ , and  $V_{CD} = \frac{V_C + V_D}{2}$ ,

and  $2 V_{BE} \approx 1.4 V$ ,  $VO2 \approx 1.1 V$

When the French or U.K. mask is selected, this transfer takes place for line currents of 30 mA to 40 mA depending on the components settings. With the Startup and Low Voltage mask, the transfer lies outside the normal operating range with line currents of 90 mA or more. In most applications the transfer from region 1 to 2 takes place for line currents below 10 mA.

With proper settings, region 4 is entered only during an overload condition. In this mode, the power consumption in the telephone set is limited. In order to detect an overload condition, the voltage between the Pins LAI and SAO is monitored. When the voltage difference is larger than the threshold VClamp1, the protection is made active. The relation for the line voltage VLP at this point is given as:

$$V_{LP} = \frac{Z0}{Z21} \times V_{Clamp1} + V_{CD} + VO2$$

When the protection mode is entered, the line current is reduced to a lower value ILP of:

$$I_{LP} = \frac{V_{Clamp2} + (VO1 - VO2)}{R1}$$

When the line voltage becomes lower than VLP, the overload condition is removed and the TCA3388 will leave region 4.

The current drawn from the line by the dc part is used to supply the TCA3388 and peripheral circuits. The excess loop current is absorbed by the voltage regulator at Pin VCC, where a filter capacitor is connected. The reference for the circuit is Pin Gnd.

Startup of the application is ensured by an internal startup circuit. When the line current flows, the hook status output pin HSO goes high. This informs the microcontroller that the set is off-hook. When the line current is no longer present the pin will go low again. Because the line current is monitored, and not the line voltage, also an interrupt of the exchange can be recognized.

## AC CHARACTERISTICS

### Impedance

In Figure 6, the block diagram of the TCA3388 performing the ac impedance is depicted. As can be seen it is partly common with the dc mask block diagram. The part generating the dc mask is replaced by a dc voltage source because for ac, this part has no influence.

Figure 6. AC Stage of the TCA3388

When calculating the ac loop, it can be derived that the set impedance Zin equals

$$Z_{in} = \frac{V_{Line}}{I_{Line}} = R1 \left( 1 + \frac{Z0}{Z21} \right) \approx R1 \times \frac{Z0}{Z21}$$

As can be noticed, the formula for the ac impedance Zin equals the formula for the dc slope in regions 1 and 3. However, because for the dc slope the resistive part of Z0 and Z21 are used, the actual values for Zin and the dc slopes do not have to be equal.

A complex impedance can be made by making either Z0 or Z21 complex. When Z0 is made complex to fit the set impedance the transmit characteristics will be complex as well. The complex impedance is therefore preferably made via the Z21 network. Because Z21 is in the denominator of the Zin formula, Z21 will not be a direct copy of the required impedance but a derivative of it. Figure 7 gives this derived network to be used for Z21.

**Figure 7. Derived Network for Z<sub>21</sub> in Case of Complex Set Impedance**

$$R_v = \frac{R_1 \times Z_0}{2(R_a + R_b - R_1)}$$

$$R_w = \frac{R_1 \times Z_0 (R_a - R_1)}{4 R_b (R_a + R_b - R_1)}$$

$$C_w = \frac{4 R_b^2 \times C_b}{R_1 \times Z_0}$$

**TRANSMIT**

When a current is injected on Pin LAI, via the loop depicted in Figure 6, a signal is created on the line. In this way the microphone signals and DTMF signals (from an external source) are transmitted. It can be derived that the signal voltage on the line ( $V_{Line}$ ) depends on the signal current injected in LAI ( $I_{LAI}$ ) according to:

$$V_{Line} = -I_{LAI} \times \frac{Z_0 \times Z_{Line}}{Z_{in} + Z_{Line}}$$

With this relation, a simplified replacement circuit can be made for the transmit amplifier (see Figure 8). Here the product of  $I_{LAI}$  and  $Z_0$  is replaced by one voltage source.

**Figure 8. Replacement Diagram for the Transmit Amplifier**

The microphone signal current is derived from the microphone signal according to the schematic in Figure 9.

**Figure 9. Microphone Amplifier Input Stage**

The input stage of Figure 9 consists of a current amplifier with transfer  $K_u$ , an input impedance of 1.0 k ( $R_{TXI}$ ), plus an attenuator which reduces the signal current at high line currents (AGC). This attenuator can be switched on/off via the microcontroller. The input current  $I_u$  within the telephony speech band is derived from the microphone signal according

$$I_u = \frac{V_u}{R_{Mic} + R_u + R_{TXI}} \approx \frac{V_u}{R_u}$$

With:  $V_u$  = signal of the microphone only loaded with  $R_{Mic}$

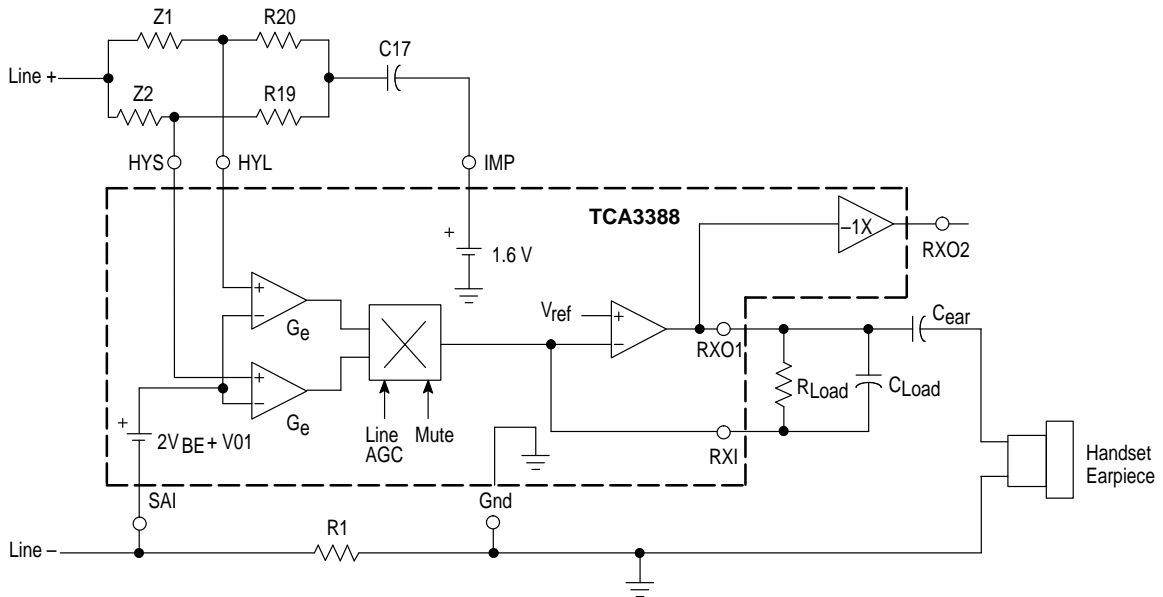

The overall gain from microphone to line ( $A_{TX}$ ) now follows as

$$A_{TX} = \frac{V_{Line}}{V_u} = \frac{K_u}{R_u} \times \frac{Z_0 \times Z_{Line}}{Z_{in} + Z_{Line}}$$

Practically, the gain can be varied only with  $Z_0$ ,  $R_u$  and  $R_{Mic}$ .

The TCA3388 offers the possibility to mute the microphone, also called privacy mode, by making the MUT Pin high. During pulse-dialing, the microphone bias is switched off. Pin Mic will be made high impedance, shutting off the microphone dc current. This reduces the current consumption of the circuit during pulse-dialing.

Figure 10. Receive Part of the TCA3388

**RECEIVE**

The receive part of the TCA3388 is shown in Figure 10.

The receive signal is picked up by the amplifiers at the HYL/HYS inputs. These are the same amplifiers present in the dc loop of Figure 5. The signal is first converted to current by the transconductance amplifier with transfer  $G_e$ . The multiplier placed after performs the line length AGC. It switches over between the 2 signals at HYS and HYL according to the line current via a modulation factor  $m$ . Afterwards, the current is converted back to voltage via the external feedback network  $Z_{Load}$ . The resulting voltage is available at output RXO1, and inverted at RXO2.

From the diagram of Figure 10 the receive gain ( $A_{RX}$ ) can be derived as:

$$A_{RX} = \frac{V_{RXO}}{V_{Line}} = G_e \times R1 \times Z_{Load} \times \left( \frac{1}{Z_H} + \frac{1}{Z_{in}} \right)$$

With:  $\frac{1}{Z_H} = \frac{R20}{R1 \times Z1}$  in case of 1 sidetone network and

HYS connected to HYL, or

$$\frac{1}{Z_H} = m \times \frac{R20}{R1 \times Z1} + (m - 1) \frac{R19}{R1 \times Z2}$$

2 sidetone networks

More information on  $Z_H$  and the modulation factor  $m$  can be found under the sidetone characteristics.

The earpiece can either be connected as a single ended or as a differential load. The above calculated gain is valid for the single ended case. When connecting as a differential load, the gain is increased by 6.0 dB. The TCA3388 offers the possibility to mute the signal coming from the line to the earpiece. This can be useful during pulse- and DTMF-dialing.

**SIDETONE**

When a transmit signal is transmitted to the line, a part of the signal is returned to the receive channel due to the architecture of the 2 to 4 wire conversion of the hybrid. During transmit, the signal on the line will be  $-I_{Line} \times Z_{Line}$ . During receive, the signal on the line will be  $I_{Line} \times Z_{in}$ . When replacing  $Z_{in}$  in the formula for the receive gain, it follows that the signal on the earpiece output due to a sending signal on the line will be:

$$\frac{V_{ear}}{V_{Line} \text{ (transmit)}} = G_e \times R1 \times Z_{Load} \times \left( \frac{1}{Z_H} - \frac{1}{Z_{Line}} \right)$$

In applications with 1 sidetone network where HYS is connected to HYL, it follows:

$$\frac{1}{Z_H} = \frac{R20}{R1 \times Z1} = \frac{1}{Z_{HL}}$$

$Z_H$  has to be chosen according the average line impedance, and the average linelength of the countries involved in the application. A complex sidetone network can be made via a complex  $Z1$  which is preferred above making  $R20$  complex. The coupling capacitor  $C17$  in series with  $R20$  is meant only to block dc.

For applications with 2 sidetone networks it follows:

$$\frac{1}{Z_H} = m \frac{R20}{R1 \times Z1} + (m - 1) \frac{R19}{R1 \times Z2} = m \frac{1}{Z_{HL}} + (m - 1) \frac{1}{Z_{HS}}$$

The  $Z_H$  thus exists as  $Z_{HL}$  for long lines with low line currents and as  $Z_{HS}$  for short lines with high line currents. This can be useful in applications such as DECT and handsfree where the sidetone has to be minimized to reduce the effect of delayed echoing and howling respectively. The TCA3388 will automatically switch over between the 2 hybrid networks as a function of line current. This is expressed in the

factor  $m$ . The relation between the line current and the factor  $m$  is depicted in Figure 11.

**Figure 11. Modulation Factor  $m$  as a Function of Line Current**

For low line currents below  $I_{Lstart}$ , thus long lines, the factor  $m$  equals 1. This means the hybrid network  $Z_{HL}$  is fully used. For high line currents above  $I_{Lstop}$ , thus short lines, the factor  $m$  equals 0. This means the hybrid network  $Z_{HS}$  is fully used. Both networks are used 50% for the intermediate line current  $I_{Lm}$ .

The switch over between the 2 networks takes place in region 3 for the French and U.K. mask and in region 2 for the Low Voltage mask.

**LINE LENGTH AGC**

The TCA3388 offers the possibility to vary the transmit and receive gain over line length in order to compensate for the loss in gain at longer line lengths. In the block diagrams of the transmit and receive channels (Figures 9, 10) the line AGC is drawn. The line AGC can be switched off by connecting a 150 kΩ resistor between HSO and Gnd. In this case, the transmit and receive gain are lowered by 2.0 dB with respect to the value calculated in the formulas above.

The line AGC characteristics for both transmit and receive channel have the general shape depicted in Figure 12.

**Figure 12. General Line AGC Characteristics**

For low line currents, and thus long lines, the gains are nominal. When the line current has increased above  $I_{Lstart}$

with a current  $I_{Lrange}$ , the gain is reduced by 6.0 dB. Due to the general characteristics of the line AGC curve, the gain will be decreased further for higher currents.

For France and U.K., the line AGC will be active in region 3 of the dc characteristics. The  $I_{Lstart}$  is approximately equal to the  $I_{LK}$ . The range is calculated from:

$$I_{Lrange} = \frac{Z1 \times (I2R - I2CD)}{R_{E3}}$$

For Low Voltage mask, the line AGC is active in region 2.

**DIALING**

Pulse-dialing is performed by making pin PI high. As a result the output LAO goes low and the loop will be disconnected. Internally the current consumption of the circuit is reduced and the current through the microphone is switched off.

DTMF-dialing is performed by supplying a DTMF signal current to Pin LAI. This is the same node where the microphone signal currents are internally applied. Therefore, for the DTMF gain the same formulas apply. Because the microphone preamplifier is bypassed, there is no influence on DTMF signals by the line length AGC.

A DTMF confidence tone can be generated on the earpiece by injecting a signal current at the RXI pin. Because only the earpiece amplifier itself is used, there are no effects from AGC or hybrid switchover.

For correct DTMF-dialing the pin MUT has to be made high. This mutes both the microphone and earphone preamplifier. In this way signals from the microphone will not be amplified to the line and signals from the line are not amplified to the earpiece.

The complete interfacing of the DTMF generator with the TCA3388 is shown in the typical application.

**SUPPORT MATERIAL**

Device Specification: Brief description of the TCA3388, block diagram, device data, test diagram, typical application

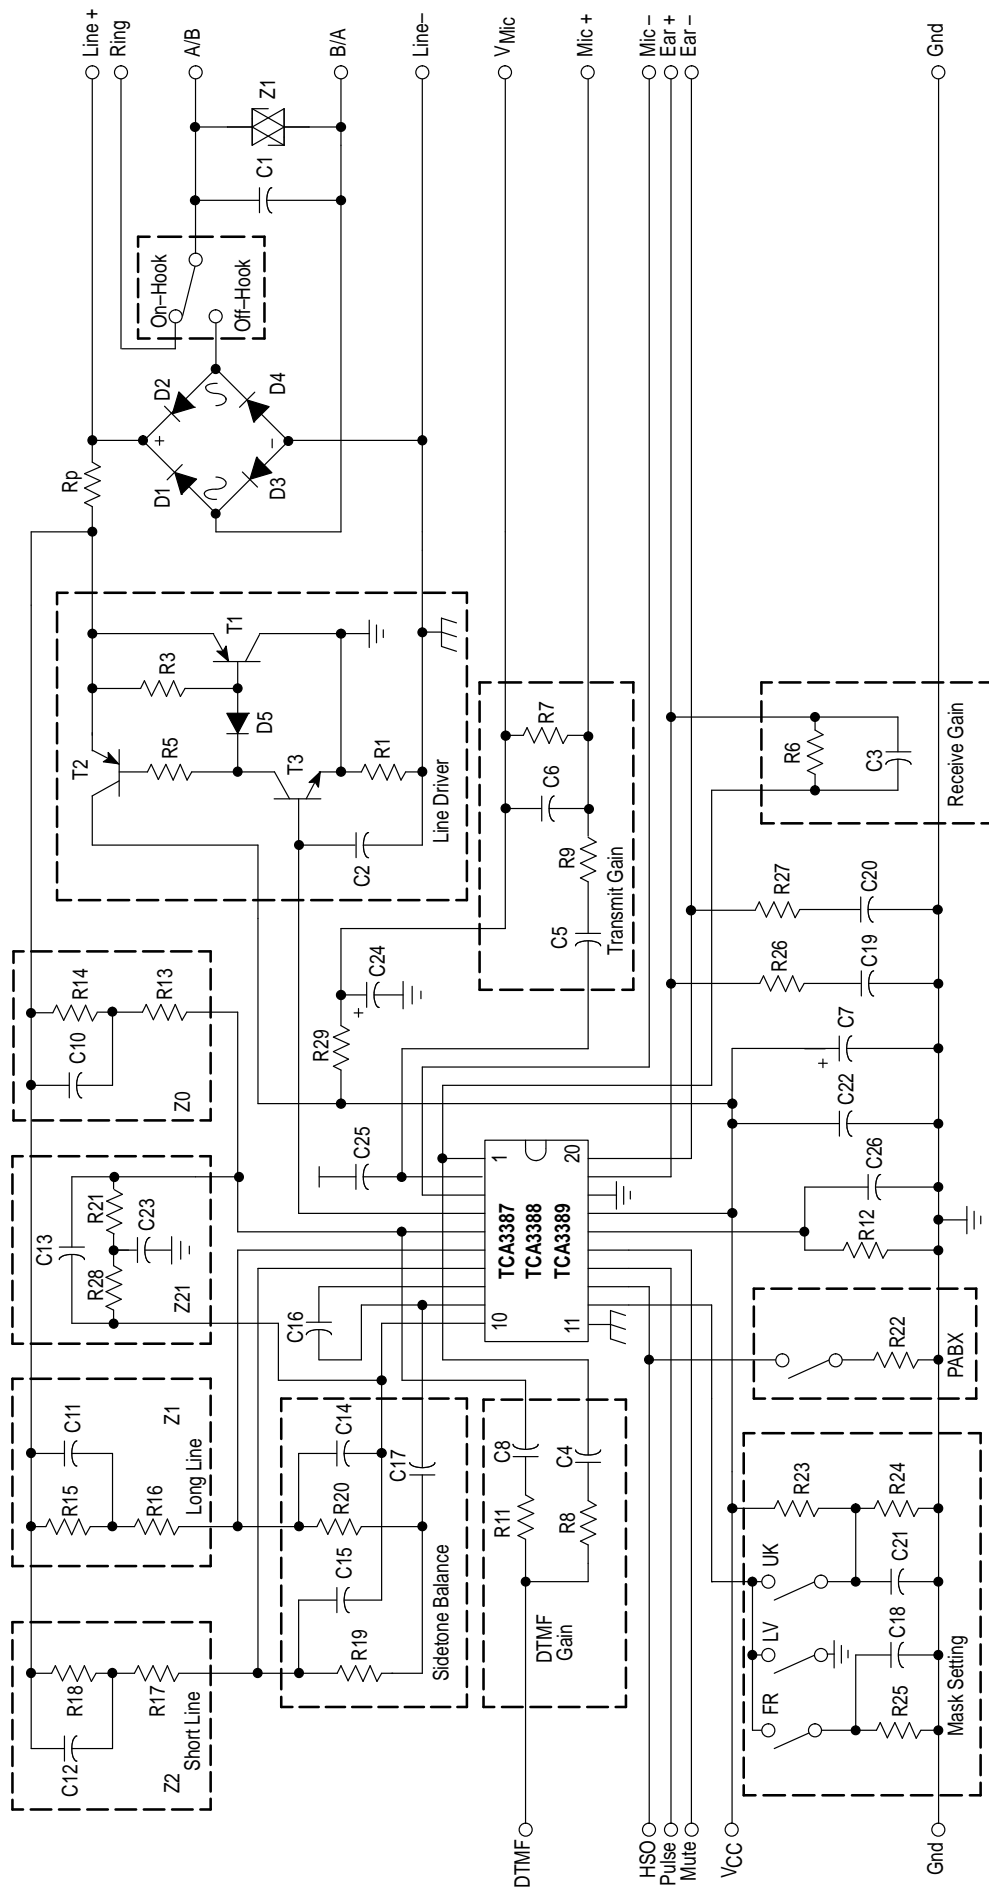

User manual TCA3388: Extended description of the circuit and its concept, adjustment procedure, application hints and proposals

Demonstration board: Shows performance of the TCA3388 in its basic application

**TYPICAL APPLICATION**

The typical application below is based on the demoboard of the TCA3388. It contains the speech transmission part, diode bridge, hook switch and microcontroller interfacing. The dc mask setting on the bottom left is given for France, U.K. and Low Voltage applications. The component values are given in the table of Figure 14. The line driver is extended with T1, D5 and R3 which increases the signal swing under low line voltage conditions.
