HIGH EFFICIENCY AUDIO PWM DRIVER

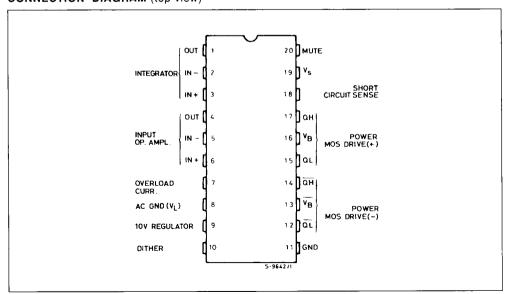

- HIGH EFFICIENCY
- P₀ = 30 W WITH POWER MOS BRIDGE
- LOW DISTORTION
- SINGLE SUPPLY OPERATION
- MUTING FACILITY
- THERMAL AND SHORT-CIRCUIT PROTECTION
- DUMP PROTECTION

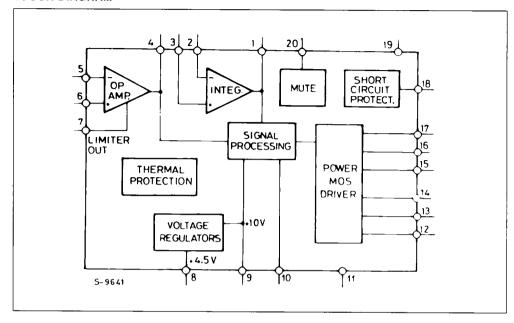

The TDA7260 is a new type of audio driver mainly intended for use in car radio applications. In conjunction with four POWER MOS in bridge configuration it can deliver 30W (d 3% R_L = 2 Ω). The device acts in "class D" as a pulse width modulation circuit. That permits a very high efficiency (> 80% at rated output power) so no heatsinks are needed. Moreover, a built-in limiter reduces the clipping effects. The TDA7260 is a monolithic integrated circuit in a 20 lead dual in line plastic package.

APPLICATION INFORMATION

Figure 18: Block Diagram.

CIRCUIT DESCRIPTION

BLOCK DIAGRAM. Fig. 18 shows the circuit block diagram. Following are described the single circuit blocks and their functions.

VOLTAGE REGULATOR. It generates two values of reference voltage, accessible even on external pins. 10 V is the voltage that supplies all the analogic internal blocks. 4,5 V (V1) is the voltage value which stands for ground of the signal inside the chip.

INPUT AMPLIFIER, INTEGRATOR, COMPARATOR WITH HYSTERESIS, N-FET BLOCK DRIVER. These components implement the control system main loop, together with the external four power devices. The TSM (two state modulation) system is used.

The input amplifier is utilized in differential configuration, and refers the input signal to V1 voltage; in

such way the chip turns to general use. On the input amplifier acts a dynamic limiter circuit, with intervention proportional to supply voltage avoiding overload and aliasing at lower V_s (Fig. 19).

Figure 19: Duty Cycle Input Dynamic Limitation.

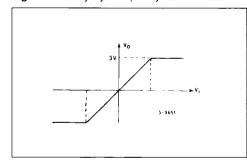

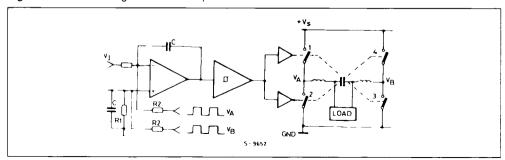

Figure 20: Free Running Oscillator Principle.

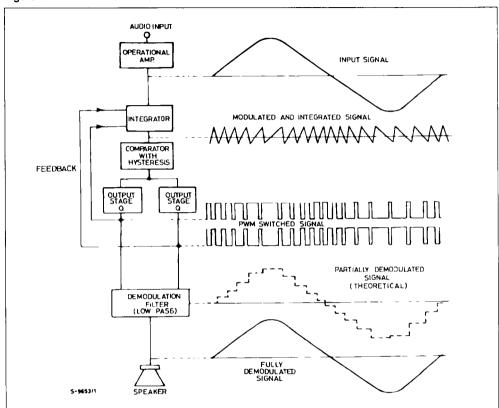

A signal for supplying an external compressor stage (i.e. TDA7232) is available.

For the effective control loop the feedback signal is taken from switched points of external power bridge (before LC output demodulation filter) and sent to

the integrator (see Fig. 20).

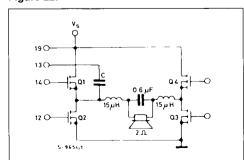

The triangle waveform at the integrator outpout drives the comparator with a hysteresis, and this supplies the correct time-intervals to the driving stages (Fig. 21).

Figure 21.

When an audio signal is introduced to the integrator, it generates an offset which varies the duty cycle and frequency of the switching output (with no audio signal the duty cycle is 50%). The bridge POWER MOS with the drain connected to the supply voltage, are driven in boostrap. The choice of MOS device is suggested by the high commutation speed and in order to reduce the chip dissipation. The Mosfets SGSP321 can be succesfully used. The LC filter on the bridge output demodulates the signal and reconstructs the sine wave on the speaker (see Fig. 22).

Figure 22.

SWITCHING FREQUENCY STABILIZER. It consists of a block which stabilizes the witching frequency of the system; it receives the supply voltage and the input signal amplitude as inputs, and accomplishes its function by varying the histeresis thresholds of the comparator. The purpose of such stabilizer is to reduce the range of the switching frequency $(40 \text{KHz} < F_{\text{sw}} < 200 \text{ KHz})$ avoiding greather variations versus supply voltage, input signal, output current. (Fig. 23).

DITHER OSCILLATOR. It is a low-frequency oscillator. Its frequency (20Hz typ.) is set by an external capacitor; at this value it determines a frequency switching modulation of about 10% around its nominal value, in order to minimize the problem of the spurious irradiations of the harmonics at the switching frequency (EMI).

Figure 23.

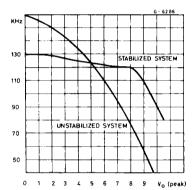

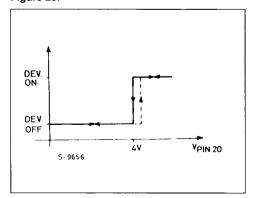

Figure 25.

MUTE.It is a protection circuit which shuts the system off when the supply voltage is lower than 10.5 V and higher than 16 V. The switching-on is further delayed by an external capacitor. In mute condition the outputs are low (Figs. 24,25).

SHORT CIRCUIT PROTECTION. It is a comparator having an offset which senses the current drawn by the power stage by a voltage drop across an external resistor (internal $V_{TH} = 250 \text{ mV}$): it acts on the mute circuit.

THERMAL AND DUMP PROTECTIONS. It shuts the device off when the junction temperature rises above 150 °C, and it has a hysteresis of above 20 °C tvp. It acts on the mute circuit.

The device is protected against supply overvoltages $(V_S = 40 \text{ V}, t = 50 \text{ ms})$.
